16 **Summary:**

17 Number of pages:45

18 Number of figures:23

19 Number of tables: 11

20 Number of texts: 4

1	<b>Figure S1.</b> Subregions in the study area. The area within the red line is the Greater London	
2	area. ....	5
3	<b>Figure S2.</b> Spatial distribution of PM monitoring stations from national networks in the UK	
4	from (a) 2010 to 2019 and (b) 1998 to 2009. Note that some clustered stations are	
5	overlapped because of their proximity. ....	6
6	<b>Figure S3.</b> Spatial distribution of PM <sub>2.5</sub> monitoring stations from regional networks in the UK	
7	from 2010 to 2019 (a) and from 2001 to 2009 (b). Note that some clustered stations are	
8	overlapped because of their proximity. ....	7
9	<b>Figure S4.</b> The spatial variation of the Euclidean distance from each grid to the left bottom	
10	corner of the study area (C1E). The blue rectangle is the rectangle around our study area.	
11	The points are the corners and the center of the rectangle. ....	13
12	<b>Figure S5.</b> Density scatterplots of the 10-fold grid-based CV results for the stage 1 model. ....	16
13	<b>Figure S6.</b> The interpretation of the stage 1 model with SHAP summary plot for PM <sub>2.5</sub>	
14	predictions in the development set (a) and feature importance of the predictors in relative	
15	percentage (b). The numbers next to the vertical axis of (a) represent mean absolute SHAP	
16	value by predictor variable. In (a), each dot in each row represents a data sample, the x	
17	position of each dot is the effect of a predictor variable on a model's prediction, and the	
18	color of the dot represents the value of that predictor variable. Dots that don't fit on the	
19	row are stacked to show density. Thirty-six predictions with PM <sub>10</sub> >100 µg/m <sup>3</sup> were	
20	removed for better visualization in (a). ....	17
21	<b>Figure S7.</b> The comparison of stage 2 model testing results based on different weights in terms	
22	of R <sup>2</sup> (a) and RMSE (c) values at the daily level and R <sup>2</sup> (b) and RMSE (d) values at the	
23	annual level. The values for different years were linked by lines for better visual display.	
24	.....	17
25	<b>Figure S8</b> Spatial variances in the stage 2 model performance in different air quality zones and	
26	agglomerations. This figure visualizes the R <sup>2</sup> values between observed and estimated	
27	PM <sub>2.5</sub> concentrations in the development set from 2010 to 2019 (a) and the testing set in	
28	2009 (b). ....	20
29	<b>Figure S9.</b> Time series in estimated (dashed) and observed (solid) monthly mean PM <sub>2.5</sub>	
30	concentrations in 4 subregions from 1998 to 2009. The correlation coefficients (r) between	
31	the observations and the predictions are shown at the bottom left of each facet. ....	21
32	<b>Figure S10.</b> Time series in observed (solid black), our model estimated (dashed blue), and	
33	EMEP4UK-simulated (longdash red) monthly mean PM <sub>2.5</sub> concentrations from 2001 to	
34	2019. The red vertical solid line is used to split the modeling years (after 2010) and the	
35	back extrapolation years (before 2010). The correlation coefficients (r) with the notation	
36	“(Predictions)” in blue shown at the bottom of each facet were calculated between the	
37	observations and our model predictions, while the correlation coefficients with the	
38	notation “(Simulations)” in red were calculated between the observations and the	
39	EMEP4UK simulations. ....	22
40	<b>Figure S11.</b> Density scatterplots of the testing results based on KCL and local networks for the	
41	stage 1 model (2010-2019) and the stage 2 model (before 2010). ....	23
42	<b>Figure S12.</b> Time series in estimated (dashed) and observed (solid) monthly mean PM <sub>2.5</sub>	
43	concentrations from 2001 to 2019 based on observations from KCL (a) and local networks	
44	(b). The red vertical solid line is used to split the modeling years (after 2010) and the back	

45 extrapolation years (before 2010). The correlation coefficients ( $r$ ) between the  
46 observations and the predictions over the 2 periods are shown at the bottom of each facet.  
47 .....25

48 **Figure S13.** Time series of estimated daily  $PM_{2.5}$  concentrations from June 13, 1982 to  
49 September 28, 1982 at Haverah Park (red) and Leeds University (blue). The 2 pollution  
50 episodes defined in the reference study<sup>30</sup> were highlighted in grey.....31

51 **Figure S14.** Effects of black carbon surface mass concentration (BCSMASS) (a) and sulfate  
52 surface mass concentration (SO4SMASS) (b) on the stage 2 model predictions in the  
53 testing set by year. The Pearson correlation coefficients ( $R$ ) between the predictor  
54 variables and their SHAP values are shown in the upper left of each facet.....32

55 **Figure S15.** Effects of 10-m u-component of wind (u10, parallel to longitude) (a) and 10-m v-  
56 component of wind (v10, parallel to latitude) (b) on the stage 2 model predictions in the  
57 testing set by year. A positive u-component of wind is from the west, while a positive v-  
58 component of wind is from the south. The vertical distribution of the data in the  
59 dependence plot indicates the interaction effects between wind direction and other  
60 predictors. Although longitude and latitude were not directly used as predictors in our  
61 study, we use the color of the dot to represent the corresponding value of longitude and  
62 latitude in (a) and (b), respectively, to show how the effects of wind vary at different  
63 locations. The Pearson correlation coefficients ( $R$ ) between the observations and the  
64 predictions over the 2 periods are shown in the upper left of each facet. ....33

65 **Figure S16.** Spatial distribution of annual average estimated  $PM_{2.5}$  concentrations in the UK  
66 from 1980 to 2019.....34

67 **Figure S17.** Spatial distribution of annual mean  $PM_{2.5}$  anomalies in the UK from 1980 to 2019.  
68 The base line was the averages in each grid over the entire period .....35

69 **Figure S18.** Spatial distribution of 4-decade seasonal average  $PM_{2.5}$  estimates in the UK. DJF:  
70 Dec, Jan, Feb; MAM: Mar, Apr, May; JJA: June, July, Aug; SON: Sept, Oct, Nov. ....36

71 **Figure S19.** Comparisons of seasonal mean  $PM_{2.5}$  and ground measured  $PM_{2.5}$  concentrations  
72 in 2009. DJF: Dec, Jan, Feb; MAM: Mar, Apr, May; JJA: June, July, Aug; SON: Sept,  
73 Oct, Nov. Obs: observations, Est: estimates.....37

74 **Figure S20.** Time series of the monthly mean  $PM_{2.5}$  anomalies from 1980 to 2019 in different  
75 subregions. The red lines with 95% confidence intervals (CIs) were derived with the  
76 locally estimated scatterplot smoothing (LOESS) approach.....38

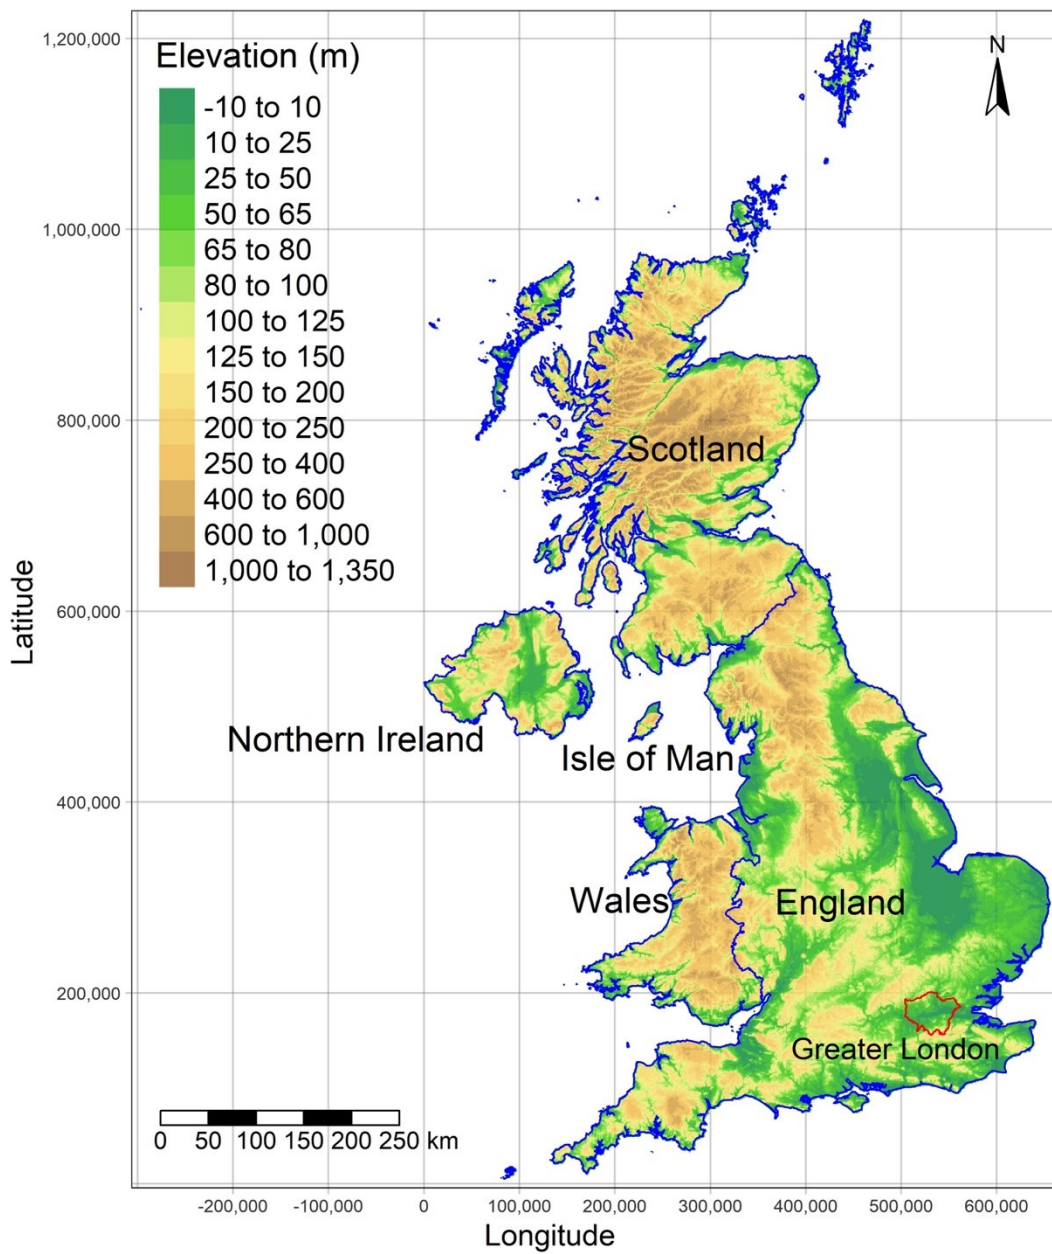

77 **Figure S21.** Time series of populations exposed to  $PM_{2.5}$  pollution from 1980 to 2019 based  
78 on two annual metrics (a) annual average and (b) the 99<sup>th</sup> percentile of the annual  
79 distribution of 24-hour average. ....40

80 **Figure S22.** Time series of normalized average concentrations of 3 types of aerosols from  
81 MERRA-2 (normalized to 1998=1) from March to May in England in the develop set of  
82 the stage 2 model .....41

83 **Figure S23.** Effects of the stage 2 model predictors on  $PM_{2.5}$  predictions from March to May  
84 2003 in England in the testing set. Only the top 4 predictors are shown separately, other  
85 predictors are aggregated. The x-axis is the ID of predictions. The y-axis is the stacked  
86 SHAP values of the predictors for each prediction. ....42

## 136 **Text S1 Data sources and preparations of auxiliary predictors**

137 Meteorological variables that played important roles in models in previous studies<sup>15, 16</sup> were  
138 obtained from three climate reanalysis data sources: the fifth generation of European ReAnalysis  
139 (ERA5), the land component of ERA5 (ERA5-Land) and HadUK-Grid. The ERA5<sup>1</sup> and ERA5-  
140 Land<sup>2</sup> datasets produced by the European Centre for Medium-Range Weather Forecasts (ECMWF)  
141 provide spatiotemporal-resolved data on a wide range of meteorological variables. HadUK-Grid is  
142 a series of datasets for daily meteorological variables at 1 km × 1 km horizontal resolution across  
143 the British Isles derived from interpolation of in-situ observations<sup>3, 4</sup>. Hourly aerosol diagnostics  
144 data of 5 types of PM<sub>2.5</sub> composition were obtained from tavg1\_2d\_aer\_Nx dataset (M2T1NXAER)  
145 <sup>17</sup> in the Modern-Era Retrospective Analysis for Research and Applications, Version 2 (MERRA-2).  
146 MERRA-2 reanalysis data were assimilated from multiple sources like model simulations, ground  
147 measurements, and satellite observations<sup>5, 18</sup>. Monthly anthropogenic source emission data were  
148 obtained from the Community Emissions Data System (CEDS) <sup>6, 7</sup> from the Pacific Northwest  
149 National Laboratory (PNNL). Pollutants selected included ammonia (NH<sub>3</sub>), nitrogen oxides (NO<sub>x</sub>),  
150 SO<sub>2</sub>, non-methane volatile organic compounds (NMVOC), and components of PM: black carbon  
151 (BC) and organic carbon (OC). Hourly predictors from ERA5, ERA5-Land, MERRA-2, and CEDS  
152 were aggregated to daily average values and then interpolated to the grid cells. Specifically, the  
153 bilinear interpolation algorithm, which has been widely used in previous studies<sup>19-21</sup>, was used for  
154 the ERA5, MERRA-2 and CEDS data. Since the spatial coverage of the ERA5-Land grid cells were  
155 slightly smaller than our modeling grids, we used another widely used algorithm<sup>22, 23</sup>, the inverse  
156 distance weighting interpolation for ERA5-Land data.

157 Land cover classification gridded maps<sup>8</sup> were obtained from the Copernicus Climate Change  
158 Service (C3S). Version 2.0.7 provides the maps from 1992 to 2015, while version 2.1.1 provides  
159 data from 2016 to 2019. The 6 types of Intergovernmental Panel on Climate Change (IPCC) classes  
160 considered for the change detection were used to aggregate the original land cover classification  
161 system<sup>24</sup>. The area proportion of each class was calculated in each 1-km grid cell. We used the land  
162 cover data in 1992 for pre-1992 years. Road network data were downloaded from OpenStreetMap,  
163 whose information was collected by participants<sup>9, 25</sup>. The length of different types of roads in each  
164 grid cell was calculated. All the years in this study used the same road density data due to data  
165 availability. Although road networks in the UK could have changed over time, we used the data in  
166 2022 to represent the overall spatial patterns of roads. Terrain including elevation<sup>10</sup> and slope<sup>11</sup> was  
167 downloaded from NASADEM and then aggregated respectively to averages in each 1 km grid cell.  
168 Gridded population and the degree of urbanization data were downloaded from the Global Human  
169 Settlement Layer (GHSL) in a 5-year time interval from 1980 to 2020 and then resampled to the  
170 modeling grid cells. The data of years without GHSL data were obtained by linear interpolation  
171 using data from the adjacent 5-year time interval. Stable nighttime light (NTL) data version 5<sup>14</sup> were  
172 obtained from a previous study<sup>26</sup> and then aggregated to averages of every 1 km grid cells. Some of  
173 the data sources used in this study went back as far as 1980, which led to the decision to limit the  
174 time span of this study.

175

176

**Figure S4.** The spatial variation of the Euclidean distance from each grid to the left bottom corner of the study area (C1E). The blue rectangle is the rectangle around our study area. The points are the corners and the center of the rectangle.

177

178

179

180

181 **Text S2 The formulas of spatiotemporal weights**

182 The formula of spatial weights is shown as follows:

183 
$$C_j E_i = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (\text{Equation S1})$$

184 Where  $C_j E_i$  represents the Euclidean distance from a grid cell  $i$  to a corner or the center  $j$  in the  
 185 study region,  $x_i, y_i$  represents the longitude and latitude of the grid cell  $i, x_j, y_j$  represents the  
 186 longitude and latitude of the corner or the center  $j$ .

187 The formula of temporal weights is shown as follows:

188 
$$IDt_{mn} = \frac{1}{|DOY_m - DOY_n| + 1} \quad (\text{Equation S2})$$

189 Where  $IDt_{mn}$  represents the inverse time interval from a day  $n$  to the middle day of a season  $n$ ,  
 190  $DOY$  represents the order of a day in a year. To avoid 0 in the denominator, add 1 to the absolute  
 191 value of the difference between the two days.

192

193 **Table S2. List of spatiotemporal weights**

Variable name	Description
C1E	The Euclidean distance from a grid to the left bottom corner of the study area
C2E	The Euclidean distance from a grid to the left top corner of the study area
C3E	The Euclidean distance from a grid to the right bottom corner of the study area
C4E	The Euclidean distance from a grid to the right top corner of the study area
CCE	The Euclidean distance from a grid to the center of the study area
dow	The order of a day in a week
IDt1	The inverse time interval from a day to the spring equinox (21 March)
IDt2	The inverse time interval from a day to the summer solstice (21 June)
IDt3	The inverse time interval from a day to the autumn equinox (22 September)
IDt4	The inverse time interval from a day to the winter solstice (22 December)

194

195 **Text S3 The LightGBM Algorithm**

196 LightGBM is a novel implementation of the gradient boosting decision trees (GBDT) algorithm.  
 197 LightGBM has three main optimization features to reduce complexity in finding the best split points  
 198 in decision trees, as is shown in the right bottom panel of Figure 1. The histogram-based algorithm,  
 199 which transforms continuous numeric features into discrete bins, is used to reduce the potential split  
 200 points. Gradient-based one-side sampling (GOSS) is used to reduce the sample size without  
 201 changing the data distribution by much. Exclusive feature bundling (EFB) is used to reduce the  
 202 number of features without hurting the accuracy<sup>27</sup>. Therefore, LightGBM has strength in faster  
 203 computation speed, lower memory consumption, and capability of handling big data when  
 204 compared with other advanced algorithms like extreme gradient boosting (XGBoost)<sup>27</sup> and has been  
 205 used in previous studies<sup>28, 29</sup>. GOSS was not used in this study due to our moderate sample size.

206

207 **Text S4 Supplementary details about the stage 1 and stage 2 models**

208 For the stage 1 model, since the model development and prediction were in grids where monitors  
 209 were available, we created a few predictors in addition to those introduced in section 2.1.3. One-hot  
 210 encoding was used to transform monitor types into new predictors. Specifically, monitor types were  
 211 defined according to whether they were in rural or suburban areas, which nation they were in  
 212 (England/Scotland), and whether they were near emission sources (background/industrial/traffic).  
 213 Since the stage 2 model needs to predict at locations where monitors were not available, predictors  
 214 derived from monitor types were excluded.

215

216 **Table S3. Hyperparameters used in this study**

Name	Long name	Values	The value selected in stage 1	The Value Selected in stage 2
learning_rate	shrinkage rate	0.05, 0.1	0.05	0.1
num_leaves	maximum number of leaves in one tree	31, 63, 127, 255, 511, 1023, 2047, 4095	4095	1023
max_depth	maximum depth for the tree model	4-12	12	12
min_data_in_leaf	minimal number of data in one leaf	10,20	20	10
bagging_fraction	the ratio of the randomly selected subset of data without resampling	0.6-1	0.85	0.90
bagging_freq	frequency for bagging	3-5	4	3
feature_fraction	the ratio of the randomly selected subset of features on each iteration	0.5-1	0.94	0.57
lambda_l1	L1 regularization	0.5,1	0.5	0.5
lambda_l2	L2 regularization	0.5,1	0.5	0.5
max_bin	Maximum number of discrete bins per feature	63,255,511	511	63

217

219 **Figure S5.** Density scatterplots of the 10-fold grid-based CV results for the stage 1 model

220

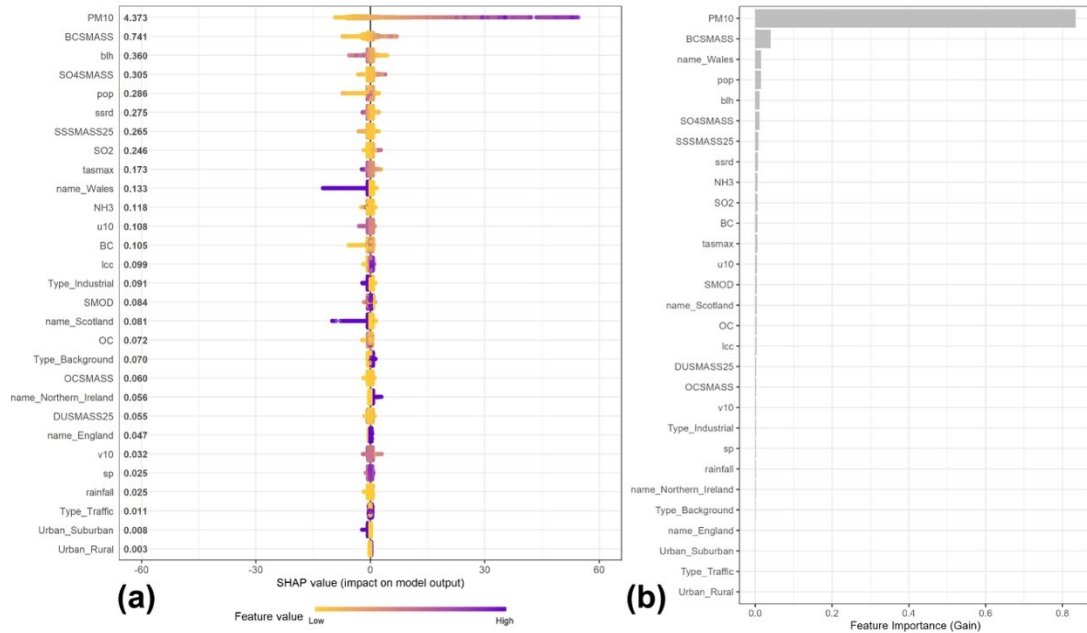

221 **Table S4. The CV results of the stage 1 model from 2010 to 2019 at the daily level**

Year	Sample size	R <sup>2</sup>	RMSE	MAE
2010	10053	0.88	3.05	2.11
2011	12606	0.92	3.05	2.20
2012	13369	0.91	2.81	2.01
2013	13174	0.90	2.77	2.00
2014	15032	0.91	2.73	1.92
2015	16927	0.89	2.43	1.57
2016	19540	0.88	2.62	1.67
2017	24435	0.91	2.05	1.35
2018	29125	0.90	2.01	1.35
2019	38178	0.93	1.88	1.18

222 Note. The unit for RMSE and MAE is µg/m<sup>3</sup>.

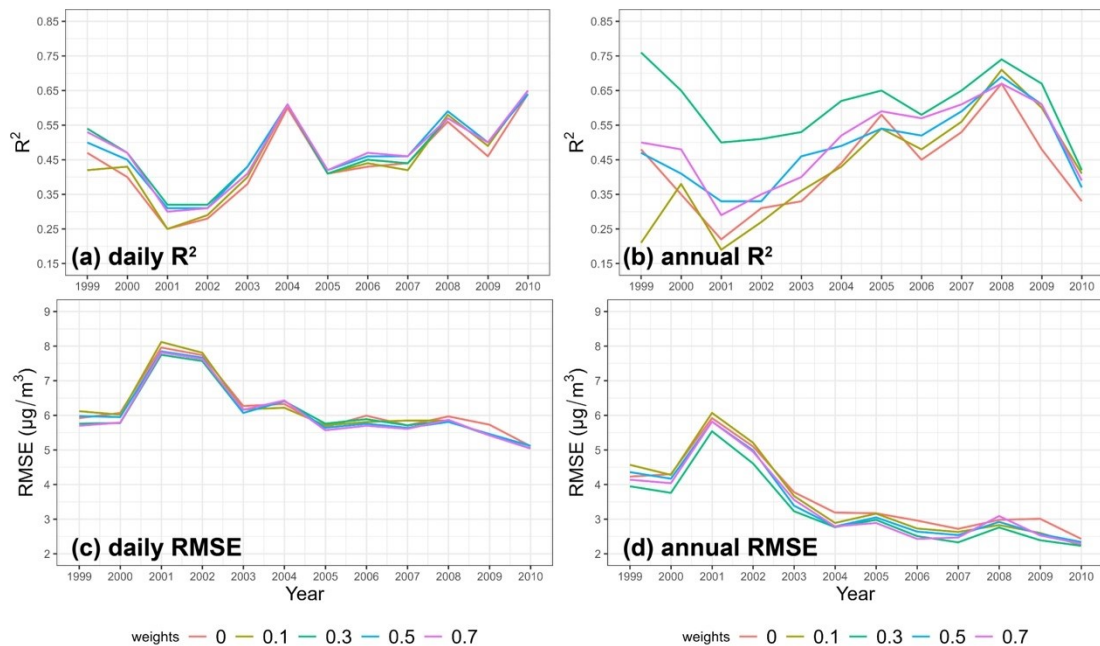

223

224

225 **Figure S6.** The interpretation of the stage 1 model with SHAP summary plot for PM<sub>2.5</sub> predictions  
 226 in the development set (a) and feature importance of the predictors in relative percentage (b). The  
 227 numbers next to the vertical axis of (a) represent mean absolute SHAP value by predictor variable.  
 228 In (a), each dot in each row represents a data sample, the x position of each dot is the effect of a  
 229 predictor variable on a model's prediction, and the color of the dot represents the value of that  
 230 predictor variable. Dots that don't fit on the row are stacked to show density. Thirty-six  
 231 predictions with PM<sub>10</sub>>100 µg/m<sup>3</sup> were removed for better visualization in (a).  
 232

233

234 **Figure S7.** The comparison of stage 2 model testing results based on different weights in terms of  
 235 R<sup>2</sup> (a) and RMSE (c) values at the daily level and R<sup>2</sup> (b) and RMSE (d) values at the annual level.  
 236 The values for different years were linked by lines for better visual display.  
 237

238

**Table S5. The by-year CV results of the stage 2 model from 2010 to 2019**

Year	Daily				Monthly average				Annual average			
	Sample size	R <sup>2</sup>	RMSE	MAE	Sample size	R <sup>2</sup>	RMSE	MAE	Sample size	R <sup>2</sup>	RMSE	MAE
2010	17660	0.63	5.30	3.35	641	0.73	2.77	2.00	55	0.78	1.85	1.34

**Figure S8** Spatial variances in the stage 2 model performance in different air quality zones and agglomerations. This figure visualizes the  $R^2$  values between observed and estimated  $PM_{2.5}$  concentrations in the development set from 2010 to 2019 (a) and the testing set in 2009 (b).

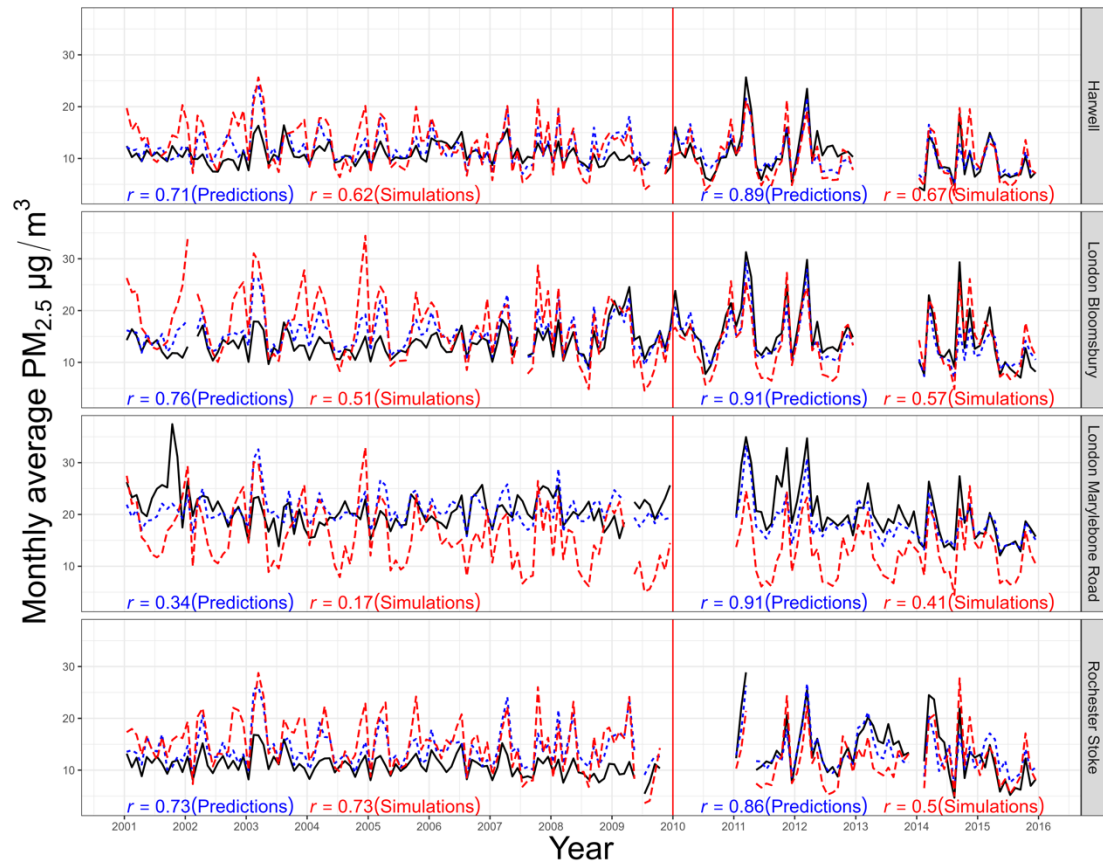

— Observations --- Predictions

256

257 **Figure S9.** Time series in estimated (dashed) and observed (solid) monthly mean PM<sub>2.5</sub>  
 258 concentrations in 4 subregions from 1998 to 2009. The correlation coefficients (r) between the  
 259 observations and the predictions are shown at the bottom left of each facet.

260

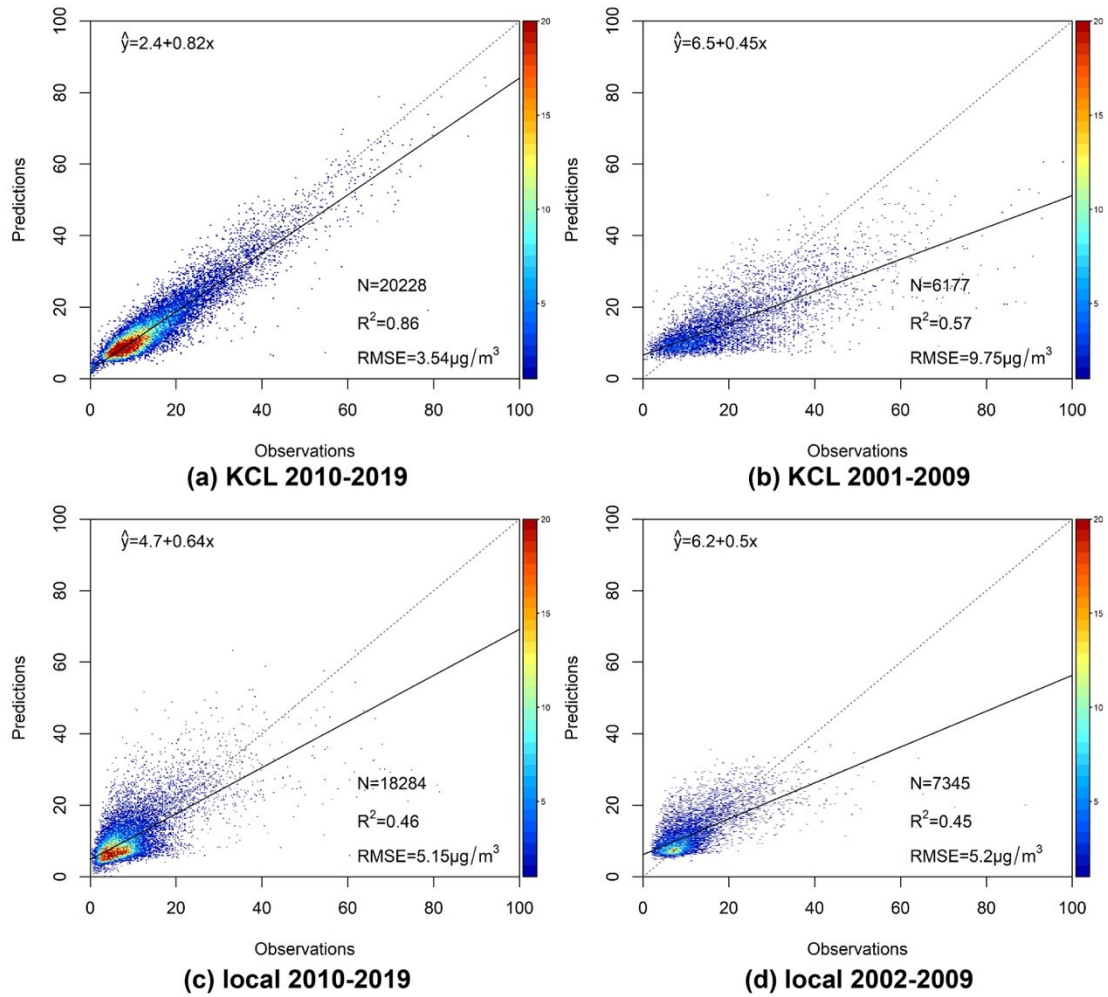

— Observations    - - - Our predictions    - - - EMEP4UK simulations

261

262 **Figure S10.** Time series in observed (solid black), our model estimated (dashed blue), and  
 263 EMEP4UK-simulated (longdash red) monthly mean PM<sub>2.5</sub> concentrations from 2001 to 2019. The  
 264 red vertical solid line is used to split the modeling years (after 2010) and the back extrapolation  
 265 years (before 2010). The correlation coefficients (r) with the notation “(Predictions)” in blue  
 266 shown at the bottom of each facet were calculated between the observations and our model  
 267 predictions, while the correlation coefficients with the notation “(Simulations)” in red were  
 268 calculated between the observations and the EMEP4UK simulations.

269

270

271 **Figure S11.** Density scatterplots of the testing results based on KCL and local networks for the  
 272 stage 1 model (2010-2019) and the stage 2 model (before 2010)

273

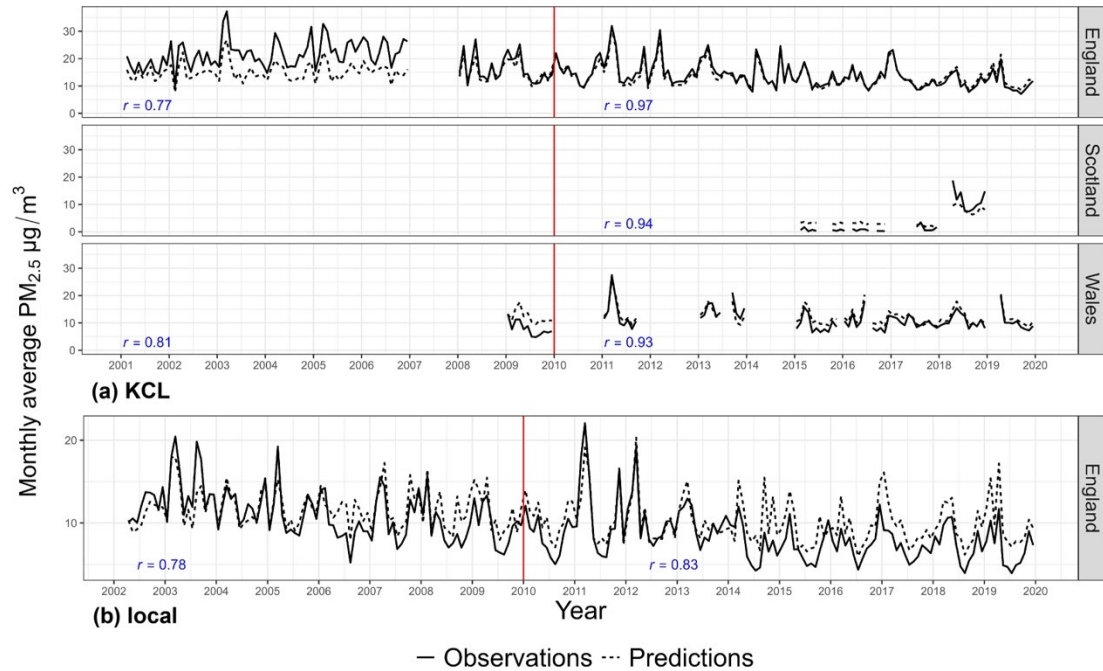

274 **Table S8. The testing results based on KCL and local networks for the stage 1 model (2010-**  
 275 **2019) and the stage 2 model (2001-2009)**

Year	KCL				local			
	Sample size	R <sup>2</sup>	RMSE	MAE	Sample size	R <sup>2</sup>	RMSE	MAE

**Figure S15.** Effects of 10-m u-component of wind (u10, parallel to longitude) (a) and 10-m v-component of wind (v10, parallel to latitude) (b) on the stage 2 model predictions in the testing set by year. A positive u-component of wind is from the west, while a positive v-component of wind is from the south. The vertical distribution of the data in the dependence plot indicates the interaction effects between wind direction and other predictors. Although longitude and latitude were not directly used as predictors in our study, we use the color of the dot to represent the corresponding value of longitude and latitude in (a) and (b), respectively, to show how the effects of wind vary at different locations. The Pearson correlation coefficients (R) between the predictor variables and their SHAP values are shown in the upper left of each facet.
